BACTERIA ATTENUATED BY A NON-REVERTING MUTATION IN EACH OF THE AROC, OMPF AND OMPC GENES, USEFUL AS VACCINES

The invention relates to attenuated bacteria useful in vaccines.

5

Background to the invention

The principle behind vaccination is to induce an immune response in the host thus providing protection against subsequent challenge with a pathogen. This may be

10 achieved by inoculation with a live attenuated strain of the pathogen, i.e. a strain having reduced virulence such that it does not cause the disease caused by the virulent pathogen.

15 Clasically, live attenuated vaccine strains of bacteria and viruses have been selected using one of two different methodologies. Mutants have been created either by

treatment of the organism using mutagenic chemical compounds or by repeated passage of the organism *in*

20 *vitro*. However, use of either method gives rise to attenuated strains in which the mode of attenuation is unclear. These strains are particularly difficult to characterise in terms of possible reversion to the wild type strain as attenuation may reflect single (easily

25 reversible) or multiple mutation events. Furthermore, it is difficult to obtain such strains having optimum immunogenic properties because of multiple mutation events, and multiple strains may need to be used to provide protection against the pathogen.

30

Using modern genetic techniques, it is now possible to construct genetically defined attenuated bacterial strains in which stable attenuating deletions can be created. A number of site directed mutants of *Salmonella* have been

35 created using this type of technology (2, 4, 5, 9, 12,

16, 17, 18). Mutations in a large number of genes have been reported to be attenuating, including the aro genes (e.g. *aroA*, *aroC*, *aroD* and *aroE*), *pur*, *htrA*, *ompR*, *ompF*, *ompC*, *galE*, *cya*, *crp* and *phoP*.

5

Salmonella *aroA* mutants have now been well characterised and have been shown to be excellent live vaccines against salmonellosis in several animal species. In addition, in order to reduce the chances of a reversion to virulence 10 by a recombination event, mutations have been introduced into two independent genes such as *aroA/purA* and *aroA/aroC*. Identical mutations in host adapted strains of Salmonella such as *S.typhi* (man) and *S.dublin* (cattle) has also resulted in the creation of a number of 15 candidate single dose vaccines which have proved successful in clinical (8, 11) and field trials (10).

A *Salmonella typhimurium* strain harboring stable mutations in both *ompC* and *ompF* is described in Chatfield 20 et al (1991, ref. 21). When administered orally to BALB/c mice the strain was attenuated, with the 50% lethal dose (LD50) reduced by approximately 1,000-fold. However, the intravenous LD50 was reduced only by approximately 10-fold, demonstrating the importance of the porins in 25 conferring on the bacteria the ability to infect by the oral route.

Expression of the *ompC* and *ompF* genes is regulated by *ompR*. Pickard et al (1994, ref. 13) describes the cloning 30 of the *ompB* operon, comprising the *ompR* and *envZ* genes, from a *Salmonella typhi* Ty2 cosmid bank and characterisation by DNA sequence analysis. The DNA sequence data were used to identify appropriate restriction sites for generating a defined deletion of

517 bp within the open reading frame of the *ompR* gene. This deletion was introduced by homologous recombination into the chromosomes of two *S.typhi* strains which already harbored defined deletions in both the *aroC* and *aroD* genes. The *S.typhi* *ompR* mutants displayed a marked decrease in *ompC* and *ompF* porin expression as demonstrated by examination of outer membrane preparations. It was also shown that the *ompR-envZ* two component regulatory system plays an important role in 10 the regulation of Vi polysaccharide synthesis in *S.typhi*.

In animal studies, attenuated *S.typhimurium* has been used as a vehicle for the delivery of heterologous antigens to the immune system (3, 6, 15). This raises the potential 15 of the development of multivalent vaccines for use in man (7).

Summary of the Invention

The invention provides a bacterium attenuated by a non-reverting mutation in each of the *aroC* gene, the *ompF* gene and the *ompC* gene. The invention also provides a vaccine containing the bacterium.

It is believed that the *aroC/ompF/ompC* combination of 25 mutations gives a vaccine having superior properties. For example, it is believed that the *aroC/ompF/ompC* combination may be superior to a *aroC/ompR* combination for two reasons:

30 1. The *ompR* mutation may cause higher levels of attenuation than the *ompF/ompC* combination of mutations because *ompR* may regulate a number of genes other than *ompF* and *ompC* which are important for survival of the bacterium *in vivo*. Thus, the

ompF/ompC combination may allow the bacterium to survive in the vaccinated host for a longer time and at higher levels, resulting in better protection.

5

2. The *ompR* mutation may cause reduced immunogenicity compared to the *ompF/ompC* combination of mutations because *ompR* may regulate the expression of antigens important for immunogenicity.

10

Detailed Description of the Invention

Bacteria useful in the Invention

The bacteria that are used to make the vaccines of the invention are generally those that infect by the oral route. The bacteria may be those that invade and grow within eukaryotic cells and/or colonise mucosal surfaces. The bacteria are generally Gram-negative.

- 20 The bacteria may be from the genera *Escherichia*, *Salmonella*, *Vibrio*, *Haemophilus*, *Neisseria*, *Yersinia*, *Bordetella* or *Brucella*. Examples of such bacteria are *Escherichia coli* - a cause of diarrhoea in humans; *Salmonella typhimurium* - the cause of salmonellosis in several animal species; *Salmonella typhi* - the cause of human typhoid; *Salmonella enteritidis* - a cause of food poisoning in humans; *Salmonella choleraesuis* - a cause of salmonellosis in pigs; *Salmonella dublin* - a cause of both a systemic and diarrhoeal disease in cattle, especially of new-born calves; *Haemophilus influenza* - a cause of meningitis; *Neisseria gonorrhoeae* - a cause of gonorrhoeae; *Yersinia enterocolitica* - the cause of a spectrum of diseases in humans ranging from gastroenteritis to fatal septicemic disease; *Bordetella*

pertussis - the cause of whooping cough; and *Brucella abortus* - a cause of abortion and infertility in cattle and a condition known as undulant fever in humans.

5 Strains of *E.coli* and *Salmonella* are particularly useful in the invention. As well as being vaccines in their own right against infection by *Salmonella*, attenuated *Salmonella* can be used as carriers of heterologous antigens from other organisms to the immune system via
10 the oral route. *Salmonella* are potent immunogens and are able to stimulate systemic and local cellular and antibody responses. Systems for driving expression of heterologous antigens in *Salmonella* *in vivo* are known; for example the *nirB* and *htrA* promoters are known to be
15 effective drivers of antigen expression *in vivo*.

The invention may be applied to enterotoxigenic *E.coli* ("ETEC"). ETEC is a class of *E.coli* that cause diarrhoea. They colonise the proximal small intestine.

20 A standard ETEC strain is ATCC H10407.

Infections of ETEC are the single most frequent cause of travellers diarrhoea, causing 3-9 million cases per year amongst visitors to developing countries. In endemic
25 areas, ETEC infections are an important cause of dehydrating diarrhoea in infants and young children, resulting in 800,000 deaths a year in the under fives world-wide. In developing countries, the incidence of ETEC infections leading to clinical disease decreases
30 with age, indicating that immunity to ETEC infection can be acquired. In contrast, naive adults from industrialized countries who visit endemic areas are highly susceptible to ETEC infections. However, with prolonged or repeated visits to endemic areas
35 susceptibility to ETEC infections diminishes, suggesting

that a live attenuated approach to ETEC vaccination may prove successful.

The inventors chose to work on a non-toxigenic strain of
5 ETEC called E1392/75/2A. E1392/75/2A arose spontaneously from a toxic mutant by deletion of toxin genes. In human studies, oral vaccination with live E1392/75/2A gave 75% protection against challenge with toxin-expressing ETEC from a different serotype. However, approximately 15% of
10 vaccinees experienced diarrhoea as a side effect of the vaccine. The strain needs further attenuation to reduce the side effects before it can be considered as a potential vaccine and the invention gives a means of achieving such attenuation.

15

Seq Id No. 1 shows the sequence of the *E.coli aroC* gene, Seq Id No. 3 shows the sequence of the *E.coli ompC* gene and Seq. Id No. 5 shows the sequence of the *E.coli ompF* gene.

20

Further mutations

One or more further mutations may be introduced into the bacteria of the invention to generate strains containing
25 mutations in addition to those in *aroC*, *ompC* and *ompF*. Such a further mutation may be (i) an attenuating mutation in a gene other than *aroC*, *ompC* and *ompF*, (ii) a mutation to provide *in vivo* selection for cells maintaining a plasmid (e.g. a plasmid expressing a
30 heterologous antigen), or (iii) a mutation to prevent expression of a toxin gene.

The further attenuating mutation may be a mutation that is already known to be attenuating. Such mutations

include mutations in *aro* genes (e.g. *aroA*, *aroD* and *aroE*), *pur*, *htrA*, *ompR*, *gale*, *cya*, *crp*, *phoP* and *surA* (see e.g. refs 2, 4, 5, 9, 12, 13, 16, 17 and 18).

5 A mutation to provide selection for maintenance of a plasmid may be made by mutating a gene that is essential for the bacterium to survive. A plasmid carrying the essential gene is then introduced into the bacterium, so that only cells carrying the plasmid can survive. This
10 may be useful where the plasmid contains, for example, a heterologous antigen to be expressed by the bacterium.

A mutation to prevent expression of a toxin gene may be made to reduce any side-effects caused by vaccination
15 with the bacterium. For example, in the case of vaccination with *E.coli* strains such as ETEC it may be desirable to mutate the heat labile toxin (LT) or heat stable toxin (ST) genes so that they are not expressed.

20 **The nature of the mutations**

The mutations introduced into the bacterial vaccine generally knock-out the function of the gene completely. This may be achieved either by abolishing synthesis of
25 any polypeptide at all from the gene or by making a mutation that results in synthesis of non-functional polypeptide. In order to abolish synthesis of polypeptide, either the entire gene or its 5'-end may be deleted. A deletion or insertion within the coding
30 sequence of a gene may be used to create a gene that synthesises only non-functional polypeptide (e.g. polypeptide that contains only the N-terminal sequence of the wild-type protein).

The mutations are non-reverting mutations. These are mutations that show essentially no reversion back to the wild-type when the bacterium is used as a vaccine. Such mutations include insertions and deletions. Insertions 5 and deletions are preferably large, typically at least 10 nucleotides in length, for example from 10 to 600 nucleotides. Preferably, the whole coding sequence is deleted.

10 The bacterium used in the vaccine preferably contains only defined mutations, i.e. mutations which are characterised. It is clearly undesirable to use a bacterium which has uncharacterised mutations in its genome as a vaccine because there would be a risk that 15 the uncharacterised mutations may confer properties on the bacterium that cause undesirable side-effects.

The attenuating mutations may be introduced by methods well known to those skilled in the art (see ref. 14). 20 Appropriate methods include cloning the DNA sequence of the wild-type gene into a vector, e.g. a plasmid, and inserting a selectable marker into the cloned DNA sequence or deleting a part of the DNA sequence, resulting in its inactivation. A deletion may be 25 introduced by, for example, cutting the DNA sequence using restriction enzymes that cut at two points in or just outside the coding sequence and ligating together the two ends in the remaining sequence. A plasmid carrying the inactivated DNA sequence can be transformed 30 into the bacterium by known techniques such as electroporation and conjugation. It is then possible by suitable selection to identify a mutant wherein the inactivated DNA sequence has recombined into the chromosome of the bacterium and the wild-type DNA 35 sequence has been rendered non-functional by homologous

recombination.

Expression of heterologous antigens

The attenuated bacterium of the invention may be
5 genetically engineered to express an antigen that is not
expressed by the native bacterium (a "heterologous
antigen"), so that the attenuated bacterium acts as a
carrier of the heterologous antigen. The antigen may be
from another organism, so that the vaccine provides
10 protection against the other organism. A multivalent
vaccine may be produced which not only provides immunity
against the virulent parent of the attenuated bacterium
but also provides immunity against the other organism.
Furthermore, the attenuated bacterium may be engineered
15 to express more than one heterologous antigen, in which
case the heterologous antigens may be from the same or
different organisms.

The heterologous antigen may be a complete protein or a
20 part of a protein containing an epitope. The antigen may
be from another bacterium, a virus, a yeast or a fungus.
More especially, the antigenic sequence may be from
E.coli (e.g. ETEC), tetanus, hepatitis A, B or C virus,
human rhinovirus such as type 2 or type 14, herpes
25 simplex virus, poliovirus type 2 or 3, foot-and-mouth
disease virus, influenza virus, coxsackie virus or
Chlamydia trachomatis. Useful antigens include non-toxic
components of *E.coli* heat labile toxin, *E.coli* K88
antigens, ETEC colonization factor antigens, P.69 protein
30 from *B.pertussis* and tetanus toxin fragment C.

The ETEC colonization factors and components thereof are
prime candidates for expression as heterologous antigens.
To instigate diarrhoeal disease, pathogenic strains of
35 ETEC must be able to colonize the intestine and elaborate

enterotoxins. For most strains of ETEC colonization factors (CF) that are required for adhesion to the intestinal mucosa have been identified. In almost all cases CFs are expressed as fimbriae on the outer surface

5 of the bacteria. A large number of CFs have been identified, the most prevalent being CFAI, CRAII (includes CS1, CS2, CS3) and CFAIV (includes CS4, CS5, CS6).

10 A vaccine to ETEC will ideally give protection against a range of colonization factor antigens to ensure that protection against different strains is obtained. In order to achieve this, it would be possible to express several colonization factors in one strain.

15 Alternatively, the same attenuations could be made in a range of different ETEC strains, each with a different colonization factor. This would involve deleting the toxins from such strains.

20 The DNA encoding the heterologous antigen is expressed from a promoter that is active *in vivo*. Two promoters that have been shown to work well in *Salmonella* are the *nirB* promoter (19, 20) and the *htrA* promoter (20). For expression of the ETEC colonization factor antigens, the

25 wild-type promoters could be used.

A DNA construct comprising the promoter operably linked to DNA encoding the heterologous antigen may be made and transformed into the attenuated bacterium using

30 conventional techniques. Transformants containing the DNA construct may be selected, for example by screening for a selectable marker on the construct. Bacteria containing the construct may be grown *in vitro* before being formulated for administration to the host for vaccination

35 purposes.

Formulation of the vaccine

The vaccine may be formulated using known techniques for formulating attenuated bacterial vaccines. The vaccine is
5 advantageously presented for oral administration, for example in a lyophilised encapsulated form. Such capsules may be provided with an enteric coating comprising, for example, Eudragate "S" (Trade Mark), Eudragate "L" (Trade Mark), cellulose acetate, cellulose phthalate or
10 hydroxypropylmethyl cellulose. These capsules may be used as such, or alternatively, the lyophilised material may be reconstituted prior to administration, e.g. as a suspension. Reconstitution is advantageously effected in a buffer at a suitable pH to ensure the viability of the
15 bacteria. In order to protect the attenuated bacteria and the vaccine from gastric acidity, a sodium bicarbonate preparation is advantageously administered before each administration of the vaccine. Alternatively, the vaccine may be prepared for parenteral administration, intranasal
20 administration or intramuscular administration.

The vaccine may be used in the vaccination of a mammalian host, particularly a human host but also an animal host. An infection caused by a microorganism, especially a
25 pathogen, may therefore be prevented by administering an effective dose of a vaccine prepared according to the invention. The dosage employed will ultimately be at the discretion of the physician, but will be dependent on various factors including the size and weight of the host
30 and the type of vaccine formulated. However, a dosage comprising the oral administration of from 10^7 to 10^{11} bacteria per dose may be convenient for a 70 kg adult human host.

Examples

The Examples described in this section serve to illustrate the invention.

5 **Brief description of the drawings**

Figure 1 shows a system for constructing defined deletions in target genes using splicing by overlay extension PCR mutagenesis.

10

Figure 2 shows the expected sequences of target genes after recombination and selection for deletions.

15 Figure 3 shows the cloning of deletion cassettes into plasmid pCVD442.

20 Figure 4 shows an SDS-PAGE analysis of outer membranes prepared from ETEC strains under conditions of low (no salt L-broth) and high (no salt L-broth + 15% sucrose) osmolarity. M = markers; Sample 1 = PTL010; Sample 2 = PTL002; Sample 3 = PTL003; Sample 4 = Δ a_{ro}C Δ ompC; Sample 5 = Δ ompF.

25 Figure 5 shows expression of CS1 and CS3 in deletion strains after growth on CFA agar. Equal numbers of cells from each strain were loaded on a 15% SDS-PAGE gel and Western blotted with monospecific anti-CS1 or anti-CS3 polyclonal antibodies. Controls for antibody specificity were whole ces11 lysates of TG1 cells expressing the 30 majore pilin protein of CS1, or purified major pilin protein from CS3. Lane M, rainbow low molecular mass markers; lane 1, induced TG1 cells harbouring pKK223; lane 2, induced TG1 cells harbouring pKKCs1; lane 3, CS1-ETEC strain; lane 4, PTL010; lane 5, PTL001; lane 6, 35 PTL002; lane 7, PTL003; lane 8, purified CS3 major pilin

protein.

Figure 6 shows a Southern blot of mutant loci.

Chromosomal DNA was extracted from the wild-type ETEC
5 (E1392/75-2A), PTL001 (htrA aroC), PTL002 (aroC ompR) and
PTL003 (aroC ompC ompF) as indicated, digested with
restriction endonuclease EcoRV, and pulsed field
electrophoresed through 1% agarose. DNA was blotted from
the gel onto Hybond N+ nylon membranes (Amersham) and
10 hybridised with DNA probes derived from the aroC, htrA,
ompR, ompC, or ompF loci as shown. The banding patterns
are consistent with the mutant loci being deletions.

Figure 7 shows the IgA responses in volunteers

15 administered a vaccine according to the invention.

EXAMPLE 1: CONSTRUCTION AND CHARACTERISATION OF STRAIN
ACCORDING TO THE INVENTION

20 **Design of deletions and construction of plasmids**

pCVDΔAroC, pCVDΔOmpC and pCVDΔOmpF

Deletions were designated to remove the entire open
reading frame of the target gene. Using the *E.coli* genome
sequence as a template, PCR primers were designed to
25 amplify fragments of 500-600 base pairs flanking the
target open reading frame (see Table 1 for primer
sequences). Splicing by overlap extension using PCR was
used to fuse the two flanking sequences, creating a PCR
product with the entire gene deleted (Figure 1). The
30 wild-type sequences around the deletion site and the
predicted sequences after deletion are depicted in Figure
2.

For each gene two different restriction sites were

introduced into the splice region (see Table 2 below). These were used for identification of deletion clones. The PCR primers at either end of the PCR fragment introduced unique restriction sites that were used to 5 clone the fragment into the multiple cloning site of pCVD442 (Figure 3).

PCR products were gel purified using a Qiagen (Trade Name) gel extraction kit and digested with the relevant 10 restriction enzymes prior to ligation to the suicide plasmid pCVD442 (22) digested with the same enzyme and treated with alkaline phosphatase to prevent vector self-ligation (Figure 3). The ligation mix was transformed into SY327 λ pir and plated on L-Ampicillin (100 µg/ml) 15 plates. Plasmids from Ampicillin resistant transformants were screened for the presence of the deletion cassettes by restriction digestion. The following plasmids were generated:

20 pCVD Δ AroC
pCVD Δ OmpC
pCVD Δ OmpF

The suicide plasmid pCVD442 can only replicate in cells 25 harboring the *pir* gene. On introduction into *non-pir* strains, pCVD442 is unable to replicate, and the Ampicillin resistance conferred by the plasmid can only be maintained if the plasmid is integrated in the chromosome by a single homologous recombination event. 30 The plasmid also has a *sacB* gene, encoding levan sucrase, which is toxic to gram negative bacteria in the presence of sucrose. This can be used to select clones that have undergone a second recombination event, in which the suicide plasmid is excised. Such cells will be resistant 35 to sucrose, but Ampicillin sensitive.

Construction and characterisation of $\Delta AroC\Delta OmpC\Delta OmpF$ strain

This section outlines the chronology of construction and history of a $\Delta AroC\Delta OmpC\Delta OmpF$ strain. In the section,

5 "ETEC" refers specifically to strain E1392/75/2A or its derivatives.

$\Delta AroC\Delta OmpC\Delta OmpF$ deletions were introduced into E1392/75/2A in the following order:

10 $\Delta AroC \rightarrow \Delta AroC\Delta OmpC \rightarrow \Delta AroC\Delta OmpC\Delta OmpF$

Construction of ETEC $\Delta AroC$

1) E1392/75/2A from original microbanked stock was plated onto L-Agar.

15 2) Electroporation competent cells were prepared from these cells. 100 μ l aliquots were frozen.

3) pCVD $\Delta AroC$ was purified from SY327pir cells using a Qiagen Qiafilter (Trade Name) midiprep. The plasmid was concentrated about 10-fold by ethanol precipitation. The construction of pCVD $\Delta AroC$ is described above.

20 4) 5 μ l of concentrated plasmid was mixed with 100 μ l defrosted cells and electroporated. The whole transformation was plated on an L-Ampicillin plate (50 μ g/ml) and incubated overnight at 37°C.

25 5) A single Ampicillin resistant colony grew.

6) The colony was streaked onto an L-Ampicillin plate (100 μ g/ml) and grown overnight at 37°C ("merodiploid plate").

30 7) PCR using primers TT19 and TT20 (specific for the *aroc* gene) and a colony picked from the merodiploid plate amplified two bands, with sizes corresponding to that of the wild-type and $\Delta aroc$ genes. The sequences of the primers are shown in Table 1

below.

8) A colony from the merodiploid plate was grown up for 7 hr in a) L-Ampicillin broth (100 µg/ml) and b) L-Broth. The colony grown on L-Ampicillin was microbanked.

5 9) Serial dilutions of the L-broth culture were set up on:

- a) No salt L-agar
- b) No salt L-agar + 5% sucrose.

10 The plates were incubated overnight at 30°C.

10) Colony counts showed that 10^4 more colonies grew on L-agar than on L-agar + 5% sucrose, showing sucrose selection worked.

11) Sucrose resistant colonies were screened for the presence of $\Delta aroC$ gene by PCR. Colonies chosen for screening were picked onto an L-agar plate and grown overnight at 37°C. This plate was stored at 4°C, whilst further tests were carried out.

15 12) 50% of 90 colonies tested had $\Delta aroC$ only.

20 13) Colonies were tested for growth on:

- a) M-9 minimal media plates
- b) M-9 minimal media + Aromix plates
- c) L-Amp (100 µg/ml)

25 $\Delta aroC$ colonies should not grow on M-9 minimal media without Aromix or on L-Amp.

Aromix is a mix of aromatic compounds as follows:

Substance	Final concentration (% w/v)
Phenylalanine	0.004
Tryptophan	0.004
Tyrosine	0.004
p-aminobenzoic acid	0.001
dihydroxybenzoic acid	0.001

These compounds are made in wild-type bacteria, but the *aroC* mutation prevents their synthesis.

14) 13/14 putative Δ AroC colonies required Aromix for growth on M-9 minimal media and were susceptible to Ampicillin.
5

15) 3 colonies (No. 1,2,3) were tested for the presence of the CS1 major pilin protein gene by PCR using primers MGR169 and MGR170. All 3 colonies gave PCR products of the expected size (700 bp.). The 10 sequences of the primers are shown in Table 1.

16) Colonies 1, 2 and 3 from screening master plate were streaked onto L-Agar and grown overnight at 37°C. Cells from these plates were used to inoculate microbank tubes.
15 17) Colony 1, stored in a microbank, was used for further work.
18) For permanent storage, a bead from the microbank tray was inoculated into 1 ml L-broth, grown for 4 hr with shaking at 37°C and used to make agar 20 slopes which were used to make freeze dried stocks. The freeze dried stock of E1392/75/2A Δ AroC was designated PTL004. 20 ml of L-broth was added to the rest of the 1 ml culture and the culture was incubated overnight at 30°C. 1 ml of the overnight 25 culture was transferred to each of three cryovials and stored in liquid nitrogen.

Construction of ETEC Δ AroC Δ OmpC

1) Preparation of pCVD Δ OmpC plasmid DNA for 30 electroporation:
A colony of SY327 λ pir harbouring pCVD Δ OmpC was grown overnight at 37°C in 100 ml L-Ampicillin broth
(100 µg/ml). Plasmid DNA was purified using 2 35 Qiagen Qiafilter (Trade Name) midipreps. DNA was

further concentrated by ethanol precipitation. The construction of pCVD Δ OmpC is described above.

2) Preparation of electrocompetent cells:

ETEC Δ AroC cells from the microbank tray produced in step 17 of the preceding section were streaked on L-agar, grown at 37°C overnight and then stored at 4°C for no more than 1 week before being used to inoculate cultures for preparing electrocompetent cells.

10 3) ETEC Δ AroC cells were electroporated with 5 μ l of concentrated pCVD Δ OmpC DNA, and each transformation plated on a single L-Ampicillin plate (50 μ g/ml) and grown overnight at 37°C.

15 4) 17 Ampicillin resistant colonies (putative ETEC Δ AroC/ pCVD Δ OmpC merodiploids) were obtained.

5) These colonies were spotted onto a master L-Ampicillin (100 μ g/ml) plate and used as templates for PCR with primers TT7/TT8. The master plate was grown at room temperature over the weekend. The sequences of the primers are given in Table 1 below.

20 6) A single colony (No. 7) had the Δ ompC gene.
7) The colony was grown for 5 hr in L-broth.
8) Serial dilutions of the L-broth culture were set up
25 on:

- a) No salt L-agar
- b) No salt L-agar + 5% sucrose.

The plates were incubated overnight at 30°C.

9) Colony counts showed that 10^4 more colonies grew on L-agar than on L-agar + 5% sucrose, showing sucrose selection worked.
30 10) 45 sucrose resistant colonies were screened for Δ ompC by PCR using primers TT7 and TT8. 9 colonies had the Δ ompC gene, but most had traces of w.t. $ompC$ gene. The sequences of the primers are given
35

in Table 1 below.

11) To further characterise putative ETEC Δ AroC Δ OmpC colonies, they were grown in 1 ml L-Broth for 5 hr and plated on:

5 a) L-Agar + 100 µg/ml Ampicillin
 b) L-Agar
 c) L-Agar + 5% sucrose

Δ OmpC colonies should be resistant to sucrose and sensitive to Ampicillin.

10 12) Only 1 colony (No. 1) was Ampicillin sensitive and sucrose resistant.

13) Colony 1 was checked for the presence of Δ aroC, Δ ompC and CS1 genes by PCR with primers TT19/TT20, TT7/TT8 and MGR169 and 170. The sequences of the

15 primers are given in Table 1 below.

14) Colony 1 gave single PCR products of the expected size for Δ aroC, Δ ompC and CS1 genes.

15) The colony was microbanked.

16) For permanent storage, a bead from the microbank

20 was inoculated into 1 ml L-broth, grown for 4 hr with shaking at 37°C and used to make agar slopes which were freeze dried. The freeze dried stock of E1392/75/2A Δ AroC Δ OmpC was designated PTL008. 20 ml of L-broth was added to the rest of the 1 ml culture and the culture was incubated overnight at 30°C. 1 ml of the overnight culture was transferred to each of three cryovials and stored in liquid nitrogen.

30 **Construction of ETEC Δ AroC Δ OmpC Δ OmpF**

Conjugation was used to introduce pCVD Δ OmpF into E1392/75/2A Δ AroC Δ OmpC.

1) Conjugation donor cells SM10λpir were transformed with pCVD Δ OmpF. The construction of plasmid

pCVD Δ OmpF is described above.

2) ETEC Δ AroC Δ OmpC cells were conjugated with SM10 λ pir/pCVD Δ OmpF cells. The pCVD442 plasmid includes a transfer origin which allows the plasmid to be transferred from a donor strain containing the RP4 transfer genes (e.g. SM10 λ pir) to a recipient strain (e.g. ETEC). ETEC Δ aroC Δ ompC cells and *E. coli* strain SM10 λ pir harbouring the Pcvd Δ ompF recombinant were cross-streaked on L-agar plates so as to cover an area of approximately 10 cm².
Plates were incubated at 37° C for 20 h, then the growth washed off using 4 ml L-broth and the suspension plated onto McConkey agar (Difco) containing streptomycin at 20 μ g ml⁻¹ and ampicillin at 300 μ g ml⁻¹. Plates were incubated overnight at 37°C and resulting colonies were checked for merodiploidy by PCR using appropriate oligonucleotides as primers.

3) Putative ETEC transconjugants were screened. 10 colonies were picked from McConkey agar plates and grown overnight on L-Ampicillin (100 μ g/ml) agar. The presence of Δ ompF gene was checked for by PCR with primers TT1/TT2. The sequences of the primers are given in Table 1 below.

25 4) The colonies were grown for 5 hr in L-broth.

5) Serial dilutions of the L-broth culture were set up on:

- a) No salt L-agar
- b) No salt L-agar + 5% sucrose.

30 6) The plates were incubated overnight at 30°C. Colony counts showed 10⁵ more colonies grew on L-agar than on L-agar + 5% sucrose, showing sucrose selection worked.

7) Sucrose resistant colonies were screened for Δ ompF gene by PCR with primers TT1/TT2. The sequences of

the primers are given in Table 1 below. The screened colonies were grown overnight on L-Agar. 3 colonies out of 47 had the Δ ompF gene with no evidence of the wild-type ompF gene.

5 8) To further characterise putative ETEC Δ AroC Δ OmpC Δ OmpF colonies, they were plated on:

- a) L-Agar + 100 µg/ml Ampicillin
- b) L-Agar
- c) L-Agar + 5% sucrose

10 Δ ompF colonies should be resistant to sucrose and sensitive to Ampicillin.

9) All three Δ ompF colonies were Ampicillin sensitive and sucrose resistant.

10) The colonies were microbanked and one colony was chosen as a master stock.

15 11) For permanent storage, a bead from the master stock was inoculated into 1 ml L-broth, grown for 4 hr with shaking at 37°C and used to make agar slopes which were used to make freeze dried stocks. The

20 freeze dried stock of E1392/75/ 2A Δ aroC Δ OmpC Δ OmpF was designated PTL003. 20 ml of L-broth was added to the rest of the 1 ml culture and the culture was incubated overnight at 30°C. 1 ml of the overnight culture was transferred to each of three cryovials 25 and stored in liquid nitrogen.

Characterisation of E1392/75/2A Δ aroC Δ OmpC Δ OmpF

1) Growth requirements:

30 Cells taken from the master stock produced in step 10 of the preceding section were streaked on L-Agar plate. At the same time 8 ml L-broth was inoculated for a chromosomal DNA prep for Southern blots. Both plate and liquid culture were grown overnight at 37°C.

35 Cells from the grown plate were streaked onto the

following media and grown overnight at 37oc.

	<u>Medium</u>	<u>Growth</u>
5	L-Amp	No
	M9 minimal media	No
	M9 minimal + Aromix	Yes
10	M9 + sulfathiazole (100 µg/ml)	No
	M9 + sulfathiazole (100 µg/ml) + Aromix	Yes
	L-Agar + 50 µg/ml streptomycin	Yes
	L-Agar + 5% sucrose	Yes

As expected, the cells were Amp sensitive. The
 15 cells were resistant to sucrose, streptomycin and
 sulfathiazole, but required Aromix to grow on
 minimal media.

2) LPS analysis of PTL003:

20 a) A freeze dried vial of PTL003 was broken open. The culture was resuspended in L-Broth and plated on L-Agar for growth. Some cells were scraped off and stored in microbank.

25 b) More cells were scraped off and the LPS profile was analysed. There was no visible difference between the LPS profile of PTL003 and original E1392/75/2A strain.

3) Confirmation of deletions by PCR:

30 a) A scrape of cells was taken from the plate made in in 2a and streaked onto L-Agar and grown overnight.

b) Freshly grown cells were used for PCR with primers that flank the following genes: *aroC*, *htrA*, *ompC*, *ompF*, *ompR*.

35 c) PTL003 was shown to have deletions in *aroC*,

ompC and *ompF* genes, but not in *htrA* or *ompR*.

4) Analysis of outer membrane protein profile of PTL003:

Outer membrane protein fractions were prepared from
5 strains PTL010 (E1392/75/2A) and the deletion strains PTL002 and PTL003. A strain with a single *ompF* deletion and a strain with both *aroC* and *ompC* deletion were also analysed. Strains were grown under conditions of low osmolarity (no salt L-broth) and high osmolarity (no salt L-broth+15% sucrose). The OmpF protein product is normally expressed at low osmolarity whereas the OmpC product is expressed at high osmolarity. The OmpC and OmpF proteins have similar electroporetic mobilities. At both high and low osmolarities, the strain PTL003 lacks proteins in the OmpC/OmpF region when compared to the wild-type E1392/75/2A strain or to the Δ AroC Δ OmpC or Δ OmpF deletion strains. The results are shown in Figure 4.

20

5) Expression of CS1 and CS3 pili on CFA agar:

The expression of CS1 and CS3 pili in the deletion strains was examined. Equal numbers (2 $A_{600\text{nm}}$ units) of bacteria strains PTL010, PTL001, PTL002 and
25 PTL003 grown overnight at 37°C on CFA agar were subjected to SDS PAGE and analysed by Western blotting with monospecific polyclonal antibodies against CS1 or CS3. CS1 and CS3 pili were expressed equally well in four strains (Figure 5).

30

A CFAII-negative derivative of E1392/75/2A was constructed for use as a control. This was done by specific curing of the CS encoding plasmids from ETEC strain E1392/75-2A. A short fragment of DNA was amplified from the *cooB* gene using PCR with

oligonucleotides CSA01 and CSA02 as primers and
ligated into pGEM-T Easy plasmid vector (Trade
Name, Promega) designed for the cloning of PCR
products. The fragment was subcloned into pCVD442
5 by virtue of the *Sal*I and *Sph*I restriction enzyme
sites. The pCVD442-*cooB* derivative was introduced
into ETEC strain E1392/75/2A by conjugation from
SM10λpir. Ampicillin resistant transconjugants are
most likely to be the result of fusion of the
10 pCVD442-*cooB* derivative with *cooB*-bearing plasmid.
Such transconjugates were then grown on L-agar
supplemented with 5% sucrose to select for loss of
the *sacB* gene of pCVD442. Resulting colonies were
tested for ampicillin sensitivity, and by PCR using
15 CSA01 and CSA02 as primers. Three colonies of
E1392/75/2A were included as positive controls
among these PCRs. Two sucrose resistant colonies
that gave no product with the PCR were streaked out
onto fresh L-agar supplemented with 5% sucrose to
20 obtain pure cultures. These were then grown in L-
broth at 37°C for approximately 16 h and
microbanked at -70°C. Loss of the CS1 encoding
plasmid was confirmed by analysis of the plasmid
profiles of the derivatives using agarose gel
25 electrophoresis. Two derivatives were confirmed as
CS1 negative, but were still CS3+.

6) Southern blotting of PTL003:
Structure of deletion mutations. Total DNA was
30 extracted from cultures of the three deletion
mutants grown from the microbanked stocks, digested
with restriction endonuclease *EcoRV*, and the
digested DNA subjected to pulsed field agarose gel
electrophoresis. DNA was blotted from the gels
35 onto Hybond N+ (Trade Name) nylon membranes and

5

hybridised with appropriate DNA probes according to standard procedures. Results (Figure 6) show that the hybridising chromosomal DNA fragments of the mutants are shorter than the wild-type, consistent with the mutations being deletions.

10

Confirmation of absence of Heat-Stable (ST) and Heat-Labile (LT) toxin genes in E.coli strain E1392/75-2A. For this the ST and LT-AB genes were used as DNA probes against total DNA from E1392/75-2A. Total DNA from the toxin positive ETEC strain E1393/75 was included as a positive control, while that from the laboratory *E.coli* strain JM109 was included as a negative. Hybridised membranes were left under Hyperfilm-ECL (Trade Name) for 1 h to obtain the maximum amount of signal. Probes were prepared using PCR with plasmid DNA extracted from E1392/75-2A as template and oligonucleotides EST01 and EST02 as primers for ST, or LT-R1 and LT-03 for LT-AB. There was no significant hybridisation with total DNA using either the LT-AB or the ST probe, despite obtaining a very intense signal from the positive control total DNA.

15

20

25

30

35

Confirmation of absence of pCVD442 sequences from the chromosome of deletion mutants. The plasmid pCVD442 was labelled and hybridised to total DNA from deletion mutants PTL001, PTL002 and PTL003 digested with EcoRV. Total DNA from ETEC strain E1392/75-2A was included as a control. A complex pattern of hybridising DNA fragments was obtained. But, there was no significant difference between the pattern obtained for the wild-type and that for the mutants, indicating that probably no residual pCVD442 nucleotide sequences were left in the genomes of the mutants. The complex pattern of

hybridising fragments was most likely due to the pCVD442 probe hybridising with the plasmid DNA components of the E1392/75-2A strain and mutant derivatives.

EXAMPLE 2: SAFETY AND IMMUNOGENICITY OF ATTENUATED VACCINE STRAIN OF ENTEROTOXIGENIC E. COLI

(ΔaroC/ΔompC/ΔompF) IN HUMAN VOLUNTEERS

The study was designed to evaluate a candidate live attenuated vaccine strain of enterotoxigenic *E. coli*, namely the Δ aroC/ Δ ompC/ Δ ompF PTL003 described above.

20

Preparation of the vaccine seed lots

The bacterial strain was plated onto MacConkey agar for 25 purity and for confirmation of identity, and 5 colonies used to inoculate a flask containing 200 ml of luria broth. After 8 hours incubation at +37°C, 30 ml of sterile glycerol was added to the broth culture and aliquots prepared (1 ml per vial). One hundred such vials were 30 frozen at -70°C. These vials constituted the seed lot for the vaccine strain.

Purity of the seed lot was ensured by selecting ten random vials, and testing them for bacterial purity and freedom from fungi. An additional three vials were tested to determine the number of bacteria in the vials using 5 standard plate count methods with serial dilutions of the culture broth.

Preparation of the vaccine

10 The vaccine was prepared fresh prior to each vaccination and all steps in the preparation of the inoculum carried out in a safety cabinet. The day prior to vaccination, 0.2 ml was spread onto the surface of luria agar plates using sterile cotton swabs to prepare the lawn of bacteria. The 15 same culture broth was streaked onto MacConkey and luria agar plates for purity. The agar plates were incubated at 37°C for 18 hours in a sealed container with tamper-resistant indicator tape to ensure that the plates were not tampered with during incubation. After incubation, the lawn 20 of bacteria was harvested with 5 ml of sterile phosphate buffered saline (PBS), and the optical density of the suspension measured. The appropriate volume of this suspension, corresponding to the desired dose, was then placed into unit dose bottles with 30 ml of bicarbonate 25 buffer and administered to the volunteers. An extra dose of vaccine was prepared and left in the laboratory, and immediately after the volunteers had been vaccinated the actual number of bacteria in each dose of vaccine was validated using standard colony count procedures with ten 30 fold dilutions of vaccine.

The procedure for diluting the bacteria was established during preliminary studies using lawn cultures prepared and incubated exactly as done for the vaccine preparations 35 administered to volunteers. Suspensions were made and the

number of viable bacteria enumerated by colony counts of serial dilutions and related to the determined optical density. Based on these preliminary studies, a standard procedure was developed for preparing and validating the
5 correct dilutions of bacteria in order to give the doses stated.

Preparation of buffer

10 A buffer consisting of sodium bicarbonate in water was used. For each dose of vaccine 150 ml of deionised water containing 2 gram of sodium bicarbonate was prepared and filter sterilised. 30 ml of the buffer was placed into 50 ml sterile vials and the dose of vaccine bacteria was added
15 to these vials. The remaining 120 ml of buffer was placed into separate sterile bottles. At the time of vaccination, the volunteers were first administered 120 ml of buffer, then a minute later, 30 ml of buffer containing the vaccine.

20

Vaccination schedule

Groups of volunteers were studied in a dose escalation manner. The first group of volunteers received a dose of
25 approximately 5×10^7 bacteria, the second a dose of approximately 5×10^9 and the third group a dose of approximately 5×10^8 .

The volunteers were given Ciprofloxacin 500 mg BID for
30 three days beginning on day 4. They were discharged on day 6, having had a haematology and chemistry screen for safety. Serum was saved for antibody measurement.

On days 9 and 14 the volunteers returned for follow-up
35 outpatient visits at which time an interval history was

done and a blood sample was obtained for serological assays. In total, blood (40 ml) was collected for serology three times, prior to vaccination and on day 9 and day 14 after vaccination.

5

Laboratory Assay Procedures

Up to two faecal specimens were cultured each day while the volunteers were in hospital. For qualitative cultures, a 10 faecal swab was placed into Cary Blair transport media and taken to the laboratory where it was inoculated directly onto MacConkey agar and onto MacConkey agar containing antibiotics selective for the vaccine strain. Up to five 15 colonies were shown to be agglutinated using antisera specific for the vaccine strain. For quantitative culture (first specimen each day only) faecal specimens were weighed and diluted in PBS, with serial 10-fold dilutions up to 10^{-4} , and then 100 μ l of each dilution was spread onto MacConkey agar with antibiotics. Suspected colonies were 20 confirmed by agglutination with anti-O serum.

Serum was collected and saved for subsequent assay for antibody against CFA II antigens by ELISA and bactericidal antibody against the vaccine strain.

25

Peripheral blood mononuclear cells were separated from whole blood collected into citrate and washed. These cells were cultured at a density of 10^7 cells per ml in RPMI tissue culture medium at 37°C for 48 hours. After 48 hours 30 the supernatant was transferred to a cryovial and frozen at -20°C until it could be assayed for IgG and IgA antibody to CFA II by ELISA.

Table 3 - Summary of the procedures of the protocol

	Day (Vaccination day is day 0)	pre	-1	0	1	2	3	4	5	6	9	14
5	Recruitment / screening	x										
	HCG (urine)	x				x						
	Training/consent	x										
10	Inpatient stay		x	x	x	x	x	x	x	x		
	Vaccination			x								
	Outpatient visit	x									x	x
15	Stool cultures - quantitative		x	x	x	x	x	x	x	x	x	x
	Stool cultures - qualitative		x	x	x	x	x	x	x	x	x	x
	Serology		x								x	x
20	CBC/Chem panel	x								x		
	Ciprofloxacin 500mg BID for 3d							x	x	x		

Results:

25 No symptoms were seen at all actual doses of 6.8×10^7 and 3.7×10^8 cfu. At the higher dose of 4.7×10^9 1/6 volunteers experienced diarrhoea and 2/6 had mild abdominal cramps. Bacterial shedding was seen in all volunteers at the 5×10^9 cfu dose level from day 1 post vaccination until, 30 as per protocol, ciprofloxacin was started on day 4 after vaccination. This indicates good intestinal colonisation, which is indicative of the potential to induce a good immune response. At the two lower doses, vaccine strain was recovered from all volunteers on at least one time 35 point following vaccination but the duration of the excretion was reduced compared to that seen at the highest dose.

At the time of filing the application, the analysis of the 40 immune responses generated by the vaccine was incomplete.

However, the IgA anti-CFA II responses in the culture supernatants of PBMNC purified from the blood of recipients of the highest dose of vaccine at day 0 (before vaccination) and days 7 and 10 post vaccination have been 5 analysed (see Figure 7). Supernatants were analysed by ELISA on assay plates coated with purified CFA II antigen. The OD values observed from the day 7 and day 10 samples were significantly higher than those from the pre-vaccination samples, demonstrating the induction of a 10 specific IgA response at these time points. As expected, the responses show a peak at day 7 and are reduced at day 10, consistent with the homing of primed IgA secreting B-cells from the blood to the mucosal effector sites of the Gut Associated Lymphoid Tissue.

15

Conclusions:

The attenuated live strain of ETEC (Δ aroC/ Δ ompC/ Δ ompF) has been shown to be well tolerated in healthy adult volunteers and to colonise the intestine in a manner 20 consistent with its utility as an oral vaccine to protect against travellers diarrhoea. It has also been demonstrated to elicit a specific mucosal immune response.

CLAIMS

1. A bacterium attenuated by a non-reverting mutation in each of the *aroC* gene, the *ompF* gene and the
5 *ompC* gene.
2. A bacterium according to claim 1 which infects by the oral route.
- 10 3. A bacterium according to claim 1 which is from the genera *Escherichia*, *Salmonella*, *Vibrio*, *Haemophilus*, *Neisseria*, *Yersinia*, *Bordetella* or *Brucella*.
- 15 4. A bacterium according to claim 3 which is a strain of *Escherichia coli*, *Salmonella typhimurium*, *Salmonella typhi*, *Salmonella enteritidis*, *Salmonella choleraesuis*, *Salmonella dublin*, *Haemophilus influenzae*, *Neisseria gonorrhoeae*,
20 *Yersinia enterocolitica*, *Bordetella pertussis* or *Brucella abortus*.
5. A bacterium according to claim 4 which is a strain of enterotoxigenic *E.coli* (ETEC).
- 25 6. A bacterium according to any one of the preceding claims which is further attenuated by a mutation in a fourth gene.

7. A bacterium according to claim 6 wherein the fourth gene is *aroA*, *aroD*, *aroE*, *pur*, *htrA*, *galE*, *cya*, *crp*, *phoP* or *surA*.

5 8. A bacterium according to any one of the preceding claims, wherein the mutation in each gene is a defined mutation.

9. A bacterium according to any one of the preceding
10 claims, wherein the mutation in each gene is deletion of the entire coding sequence.

10. A bacterium according to any one of the preceding claims which has been genetically engineered to
15 express a heterologous antigen.

11. A bacterium according to claim 10, wherein expression of the antigen is driven by the *nirB* promoter or the *htrA* promoter.

20

12. A vaccine comprising a bacterium as defined in any one of the preceding claims and a pharmaceutically acceptable carrier or diluent.

25 13. A bacterium as defined in any one of claims 1 to 11 for use in a method of vaccinating a human or animal.

14. An enterotoxigenic *E.coli* cell attenuated by a non-
30 reverting mutation in each of the *aroC* gene, the

ompF gene and the *ompC* gene, for use in a method of vaccinating a human or animal against diarrhoea.

15. Use of a bacterium as defined in any one of claims
5 1 to 11 for the manufacture of a medicament for
vaccinating a human or animal.

16. A method of raising an immune response in a
mammalian host, which comprises administering to
10 the host a bacterium attenuated by a non-reverting
mutation in each of the *aroC* gene, the *ompF* gene
and the *ompC* gene.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/GB 99/00935

A. CLASSIFICATION OF SUBJECT MATTER

IPC 6 C12N15/03 C12N1/20 C12N15/31 A61K39/108 // (C12N1/20, C12R1:19)

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12N A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	CERSINI A. ET AL: "Intracellular multiplication and virulence of <i>Shigella flexneri</i> auxotrophic mutants." INFECT AND IMMUNITY, (1998) 66/2 (549-557). , XP002112173 the whole document ----	1-13, 15, 16
Y	COBOS A ET AL: "TRANSPOSON-GENERATED TN10 INSERTION MUTATIONS AT THE ARO GENES OF <i>ESCHERICHIA- COLI</i> K-12." CURR MICROBIOL, (1990) 20 (1), 13-18. , XP002112174 the whole document ----	1-16 -/-

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.

PCT/GB 99/00935

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claim 16
is directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

The additional search fees were accompanied by the applicant's protest.
 No protest accompanied the payment of additional search fees.
